1. transcription elongation

2. ...in eukaryotic chromatin

3. transcription in condensed chromatin?

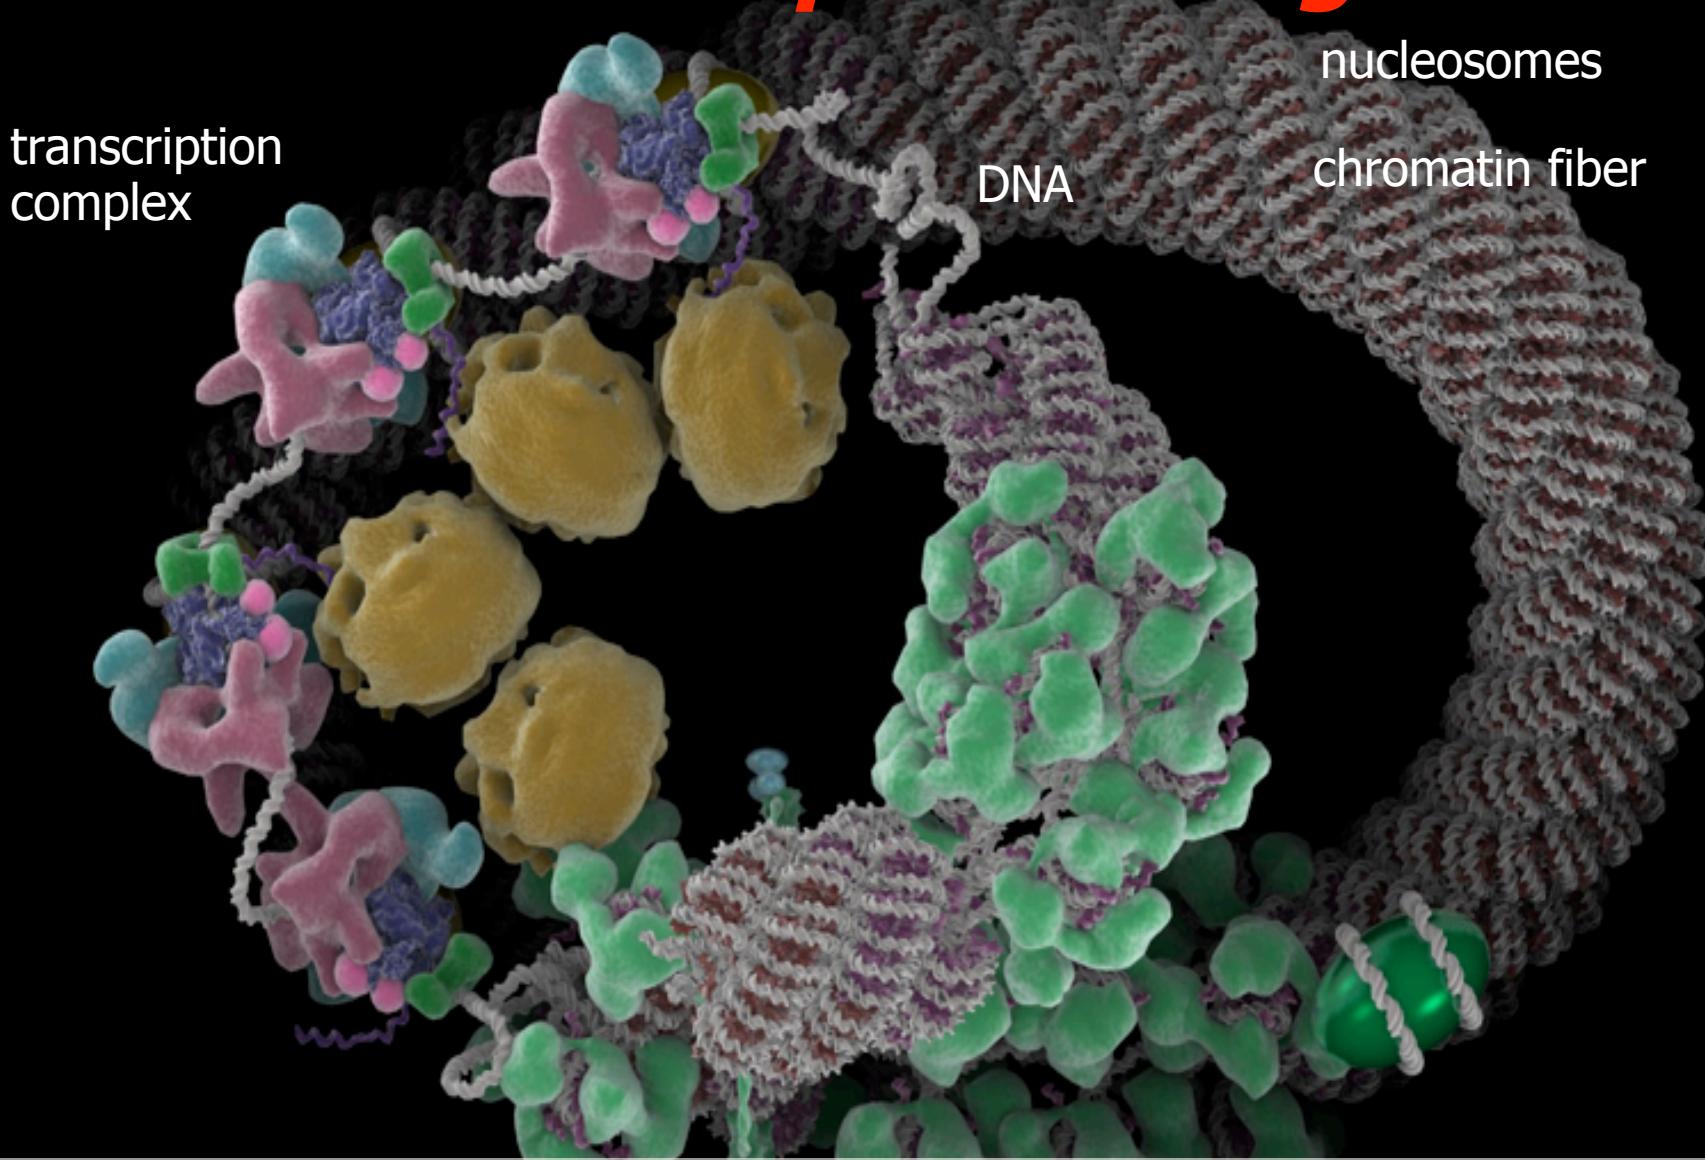

4. what about nucleosomes?

5. probing nucleosomes under torsion

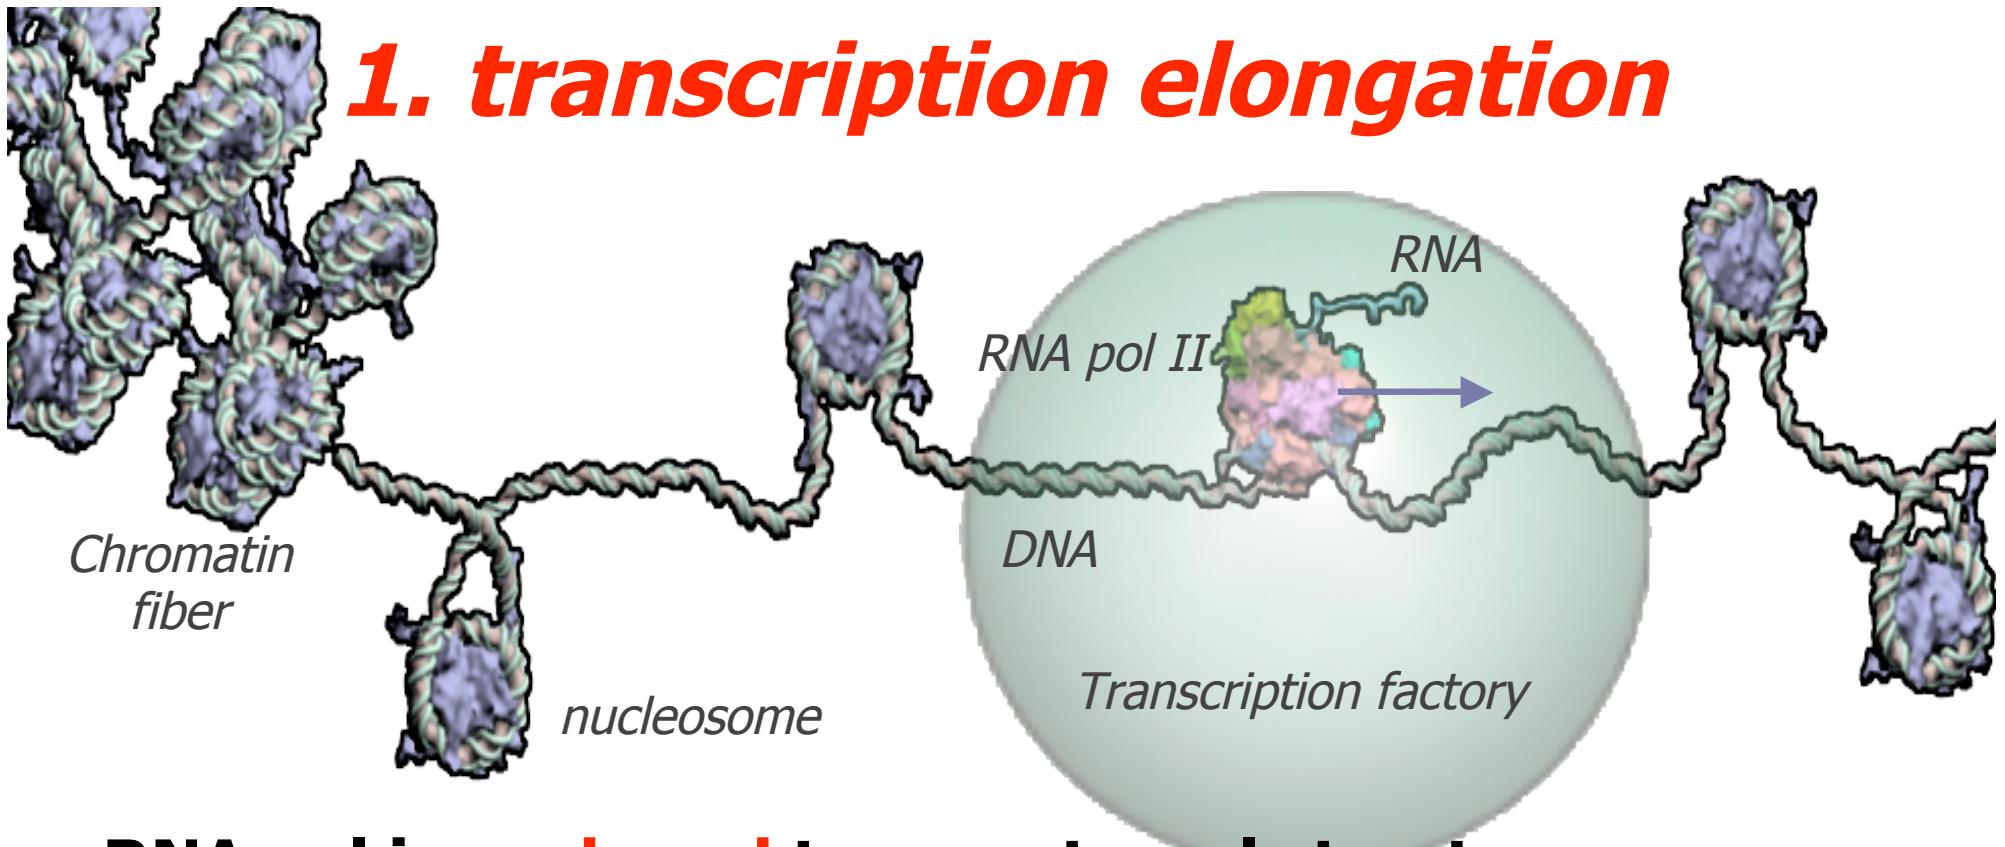

6. back to transcription

7. resulting scenario

1. transcription elongation

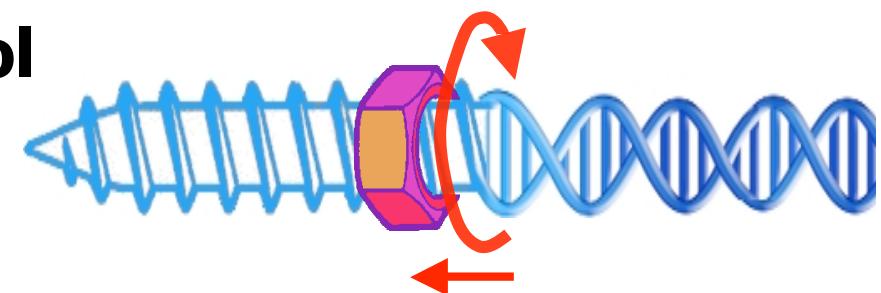

- Are **nucleosomes** significant **obstacles** for RNA pol?
- How is the **chromatin fiber** modified during transcription?

RNA pol is anchored to an external structure

⇒ DNA **screws** through RNA pol

rate: $\omega_0 \sim 2$ turns/sec
 $(V \sim 20$ bps/sec)

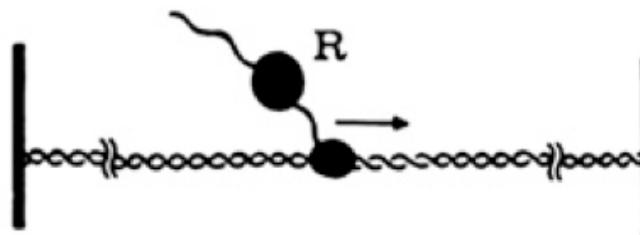

↔ RNA pol II exerts a torque > 5 pN·nm (Harada 2001)
 < 40 pN·nm ($kT \sim 4$ pN·nm)

1. transcription elongation

⇒ topological consequences:

generation of positive/negative supercoiling
ahead/behind the RNA pol (~2 turns/sec)

in prokaryotes:

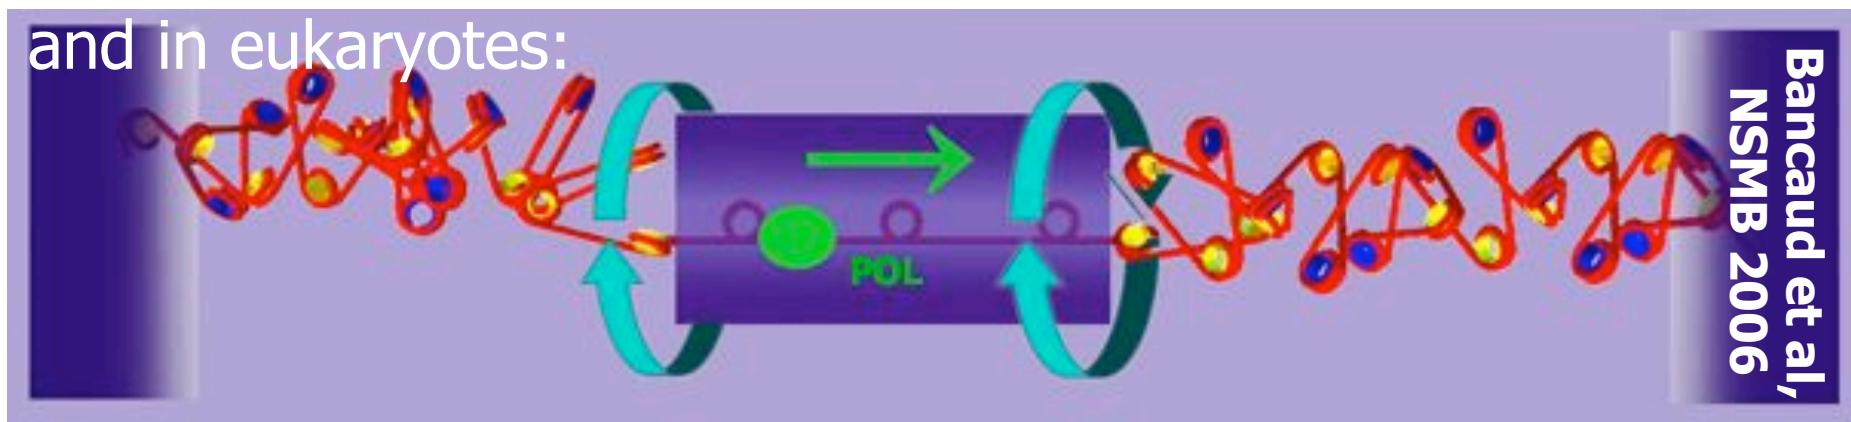

Twin-supercoiled domain model

(Liu & Wang, PNAS 1987)

and in eukaryotes:

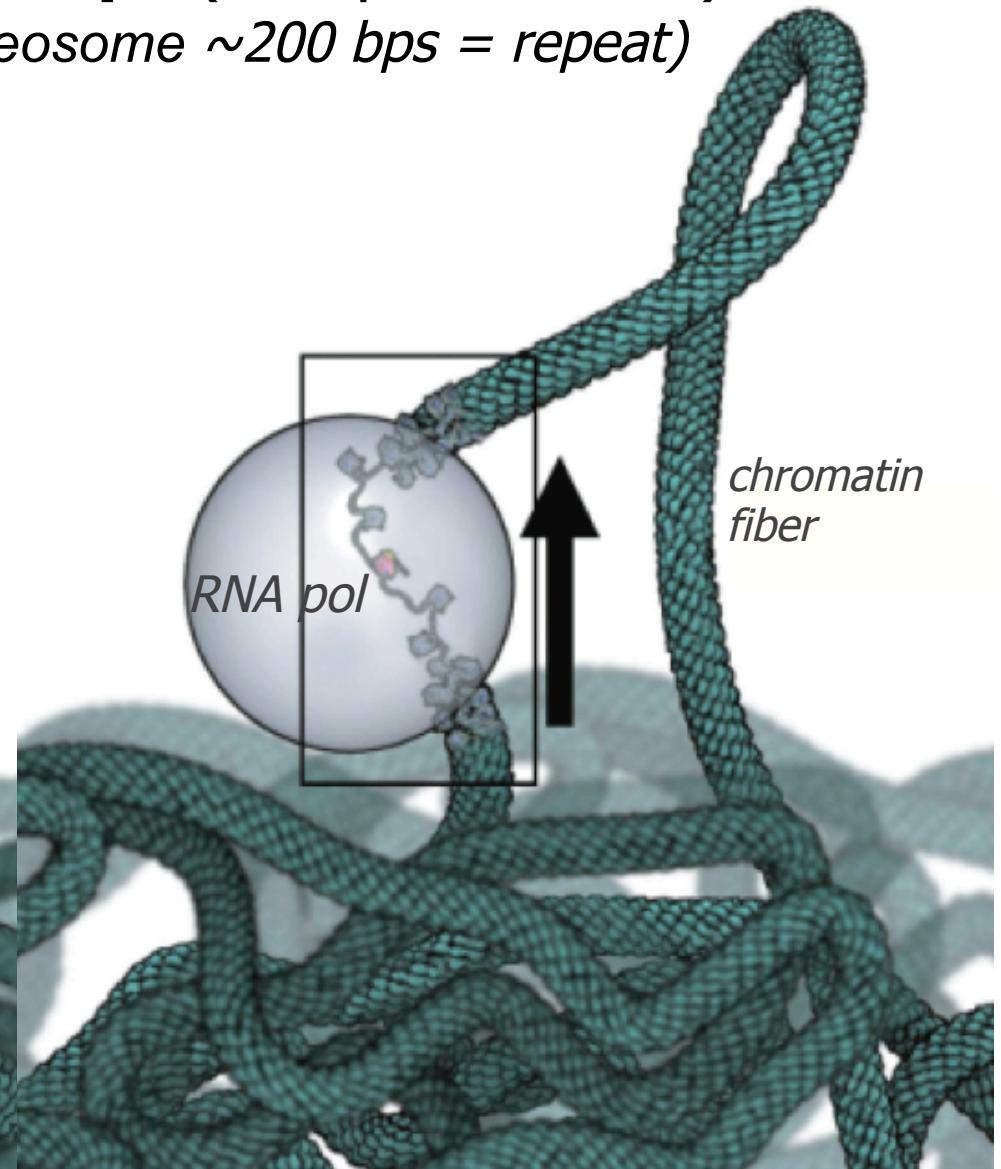

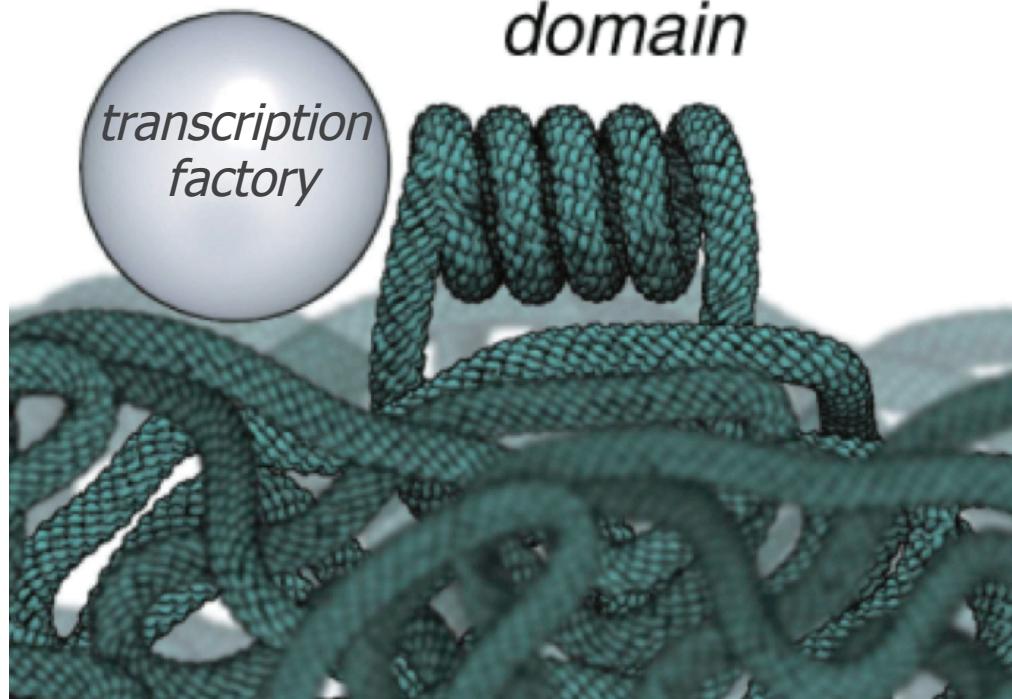

Bancaud et al,
NSMB 2006

2. ...in eukaryotic chromatin

- chromatin fiber is organized in **loops** (clamped at ends) of N~250 nucleosomes (1 nucleosome ~200 bps = repeat)

⇒ linking number conservation
in a *chromatin loop domain*

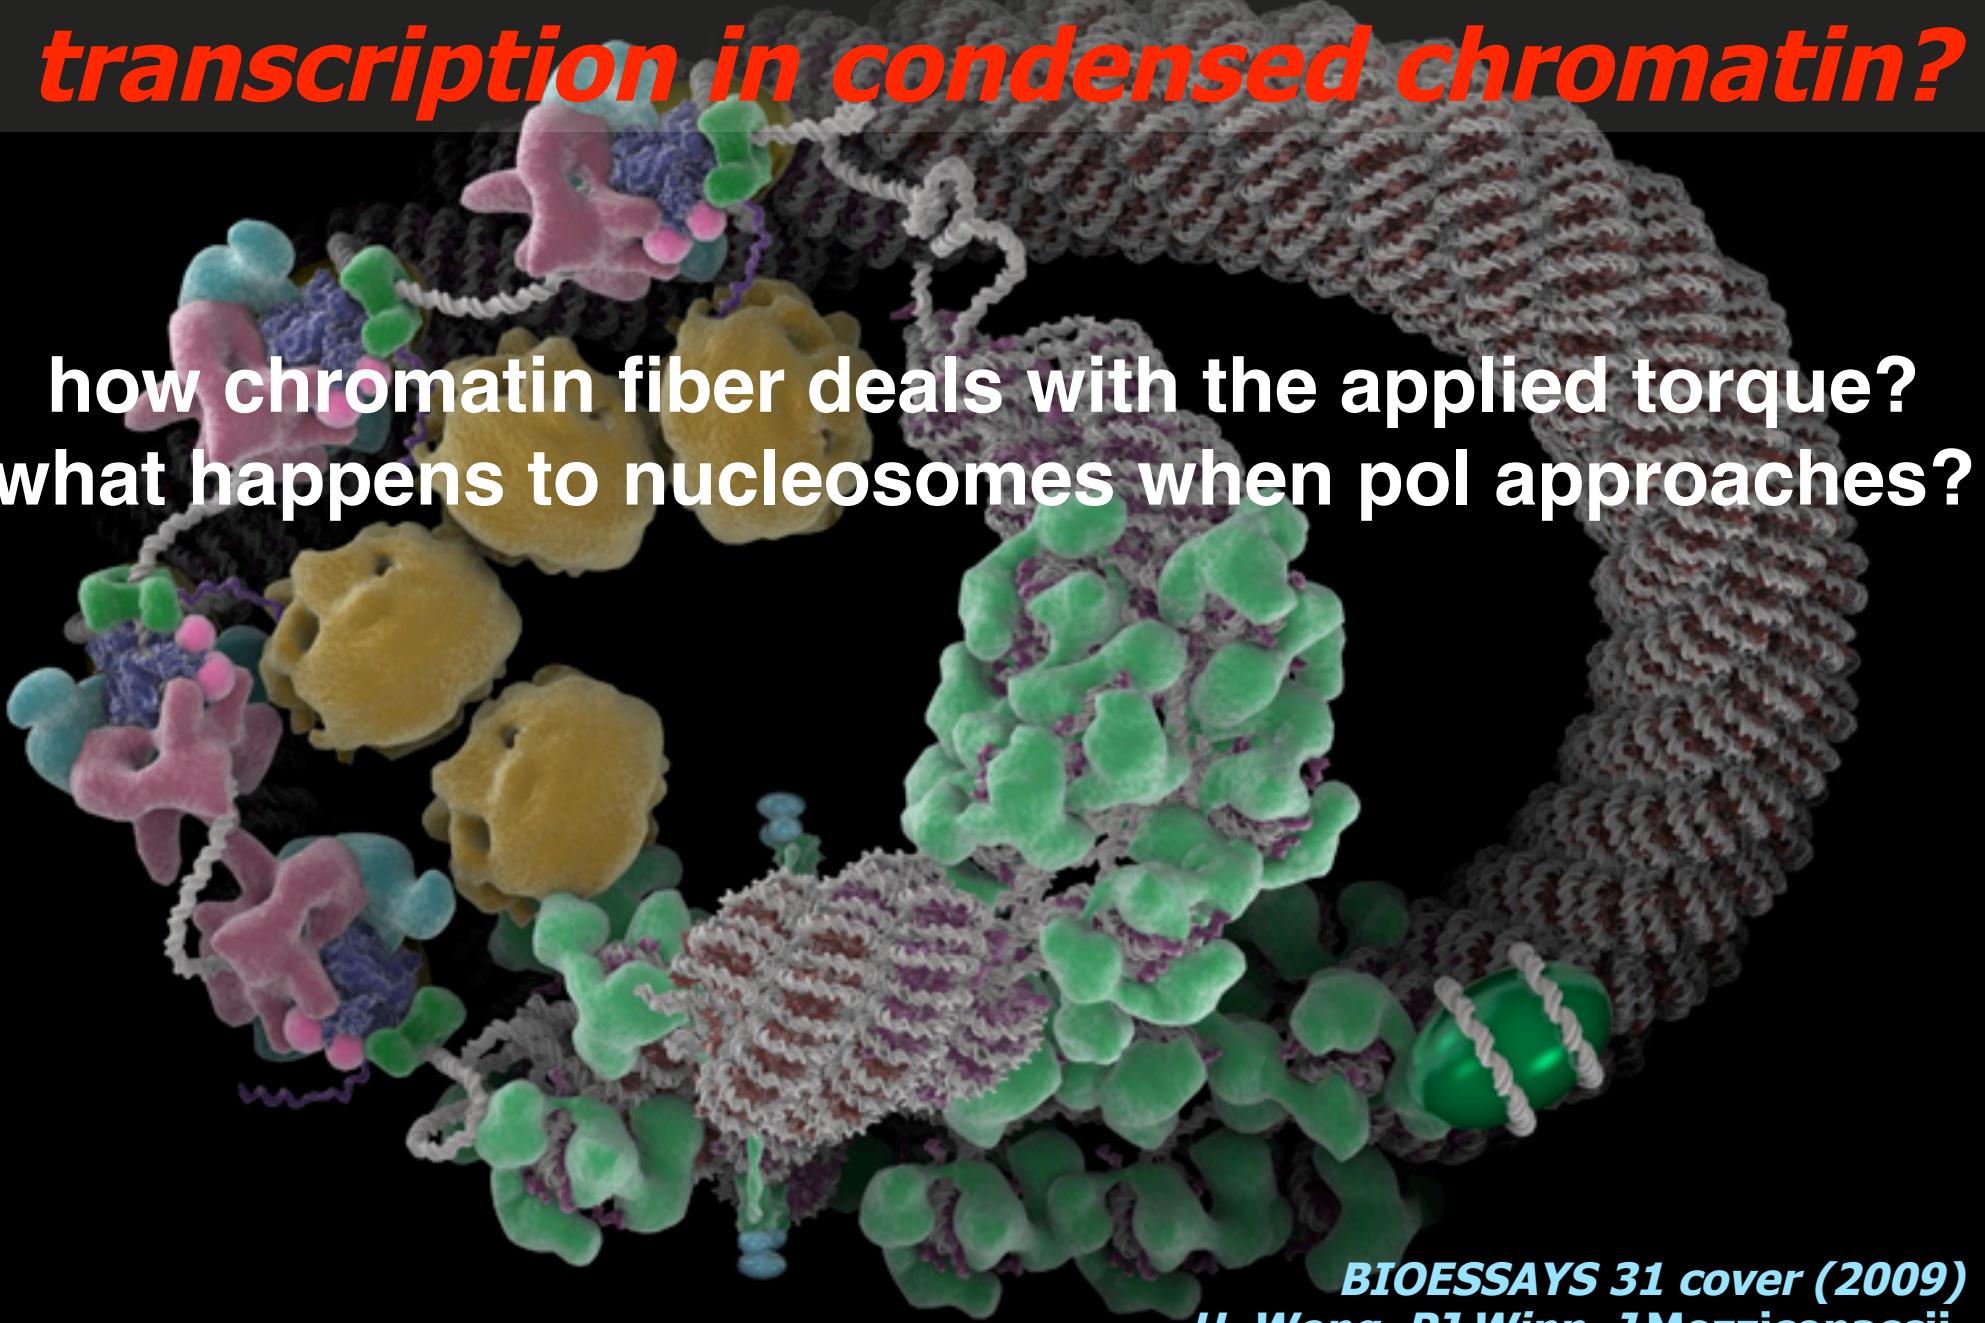

Figures by H. Wang for C. Lavelle, Biochem Cell Biol 87:307-322 (2009) .

3. no evidence for decondensation prior to transcription:

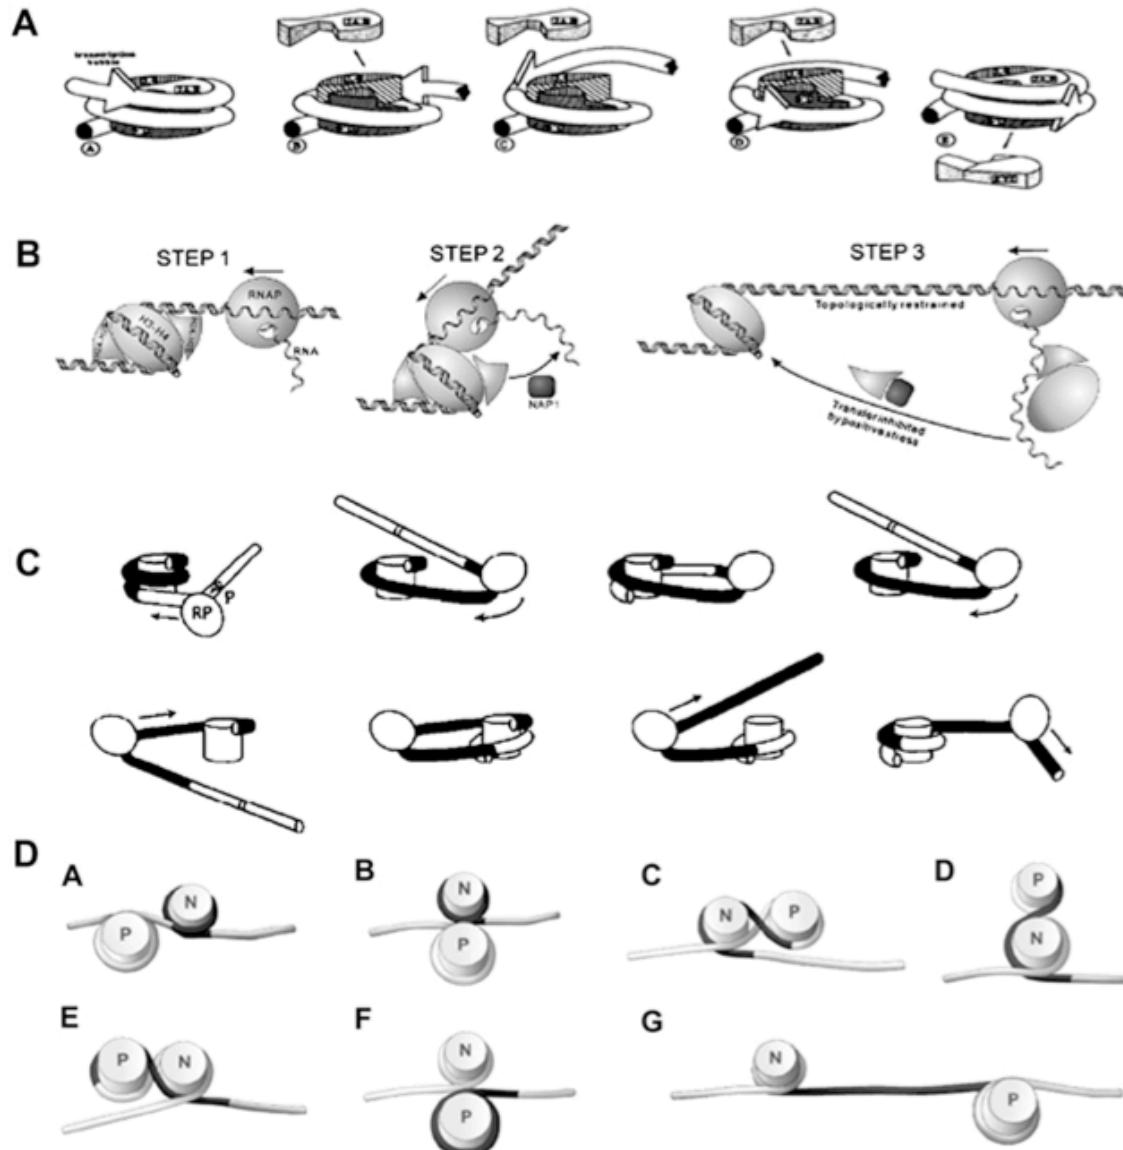

transcription in condensed chromatin?

how chromatin fiber deals with the applied torque?
what happens to nucleosomes when pol approaches?

BIOESSAYS 31 cover (2009)
H. Wong, PJ Winn, J Mozziconacci

4. what about nucleosomes?

how RNA pol get
through nucleosomes
during transcription?

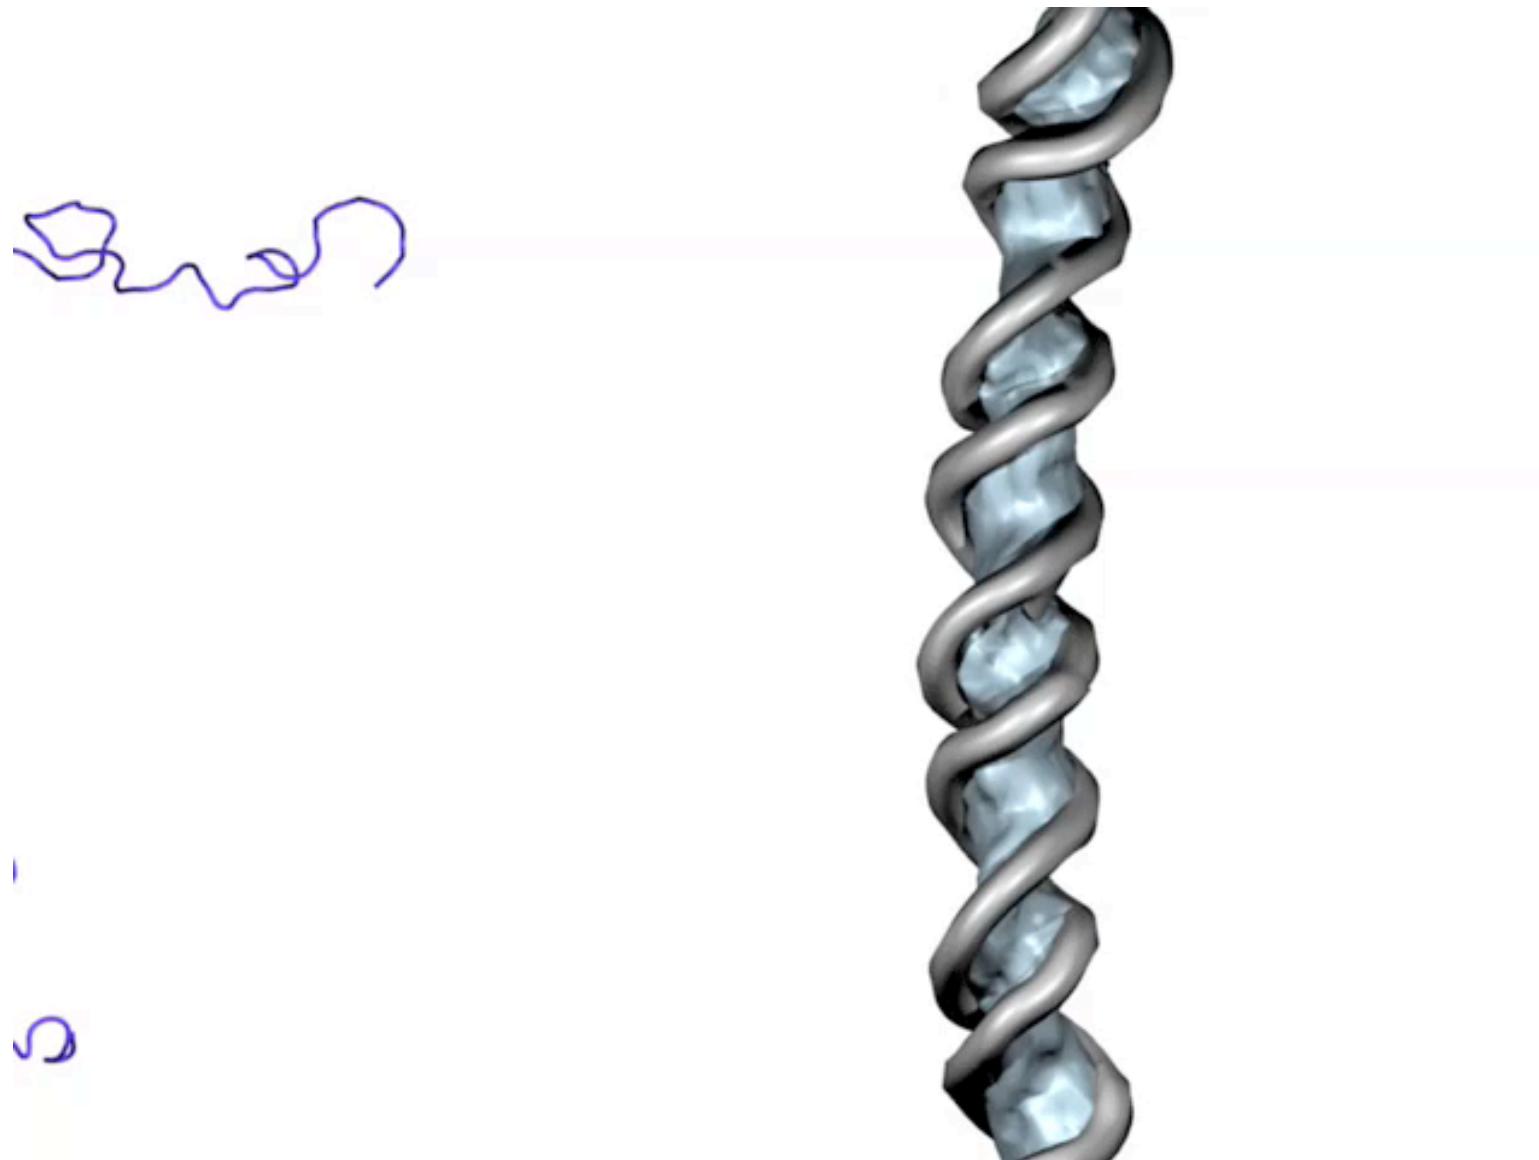

→ many models!

→ need for an
destabilized state
of the nucleosome

- histone release,
- nucleosome translocation,
- DNA unwrapping,
- nucleosome distortion...

RNA pol II :
H2A-H2B destabilization
no octamer translocation

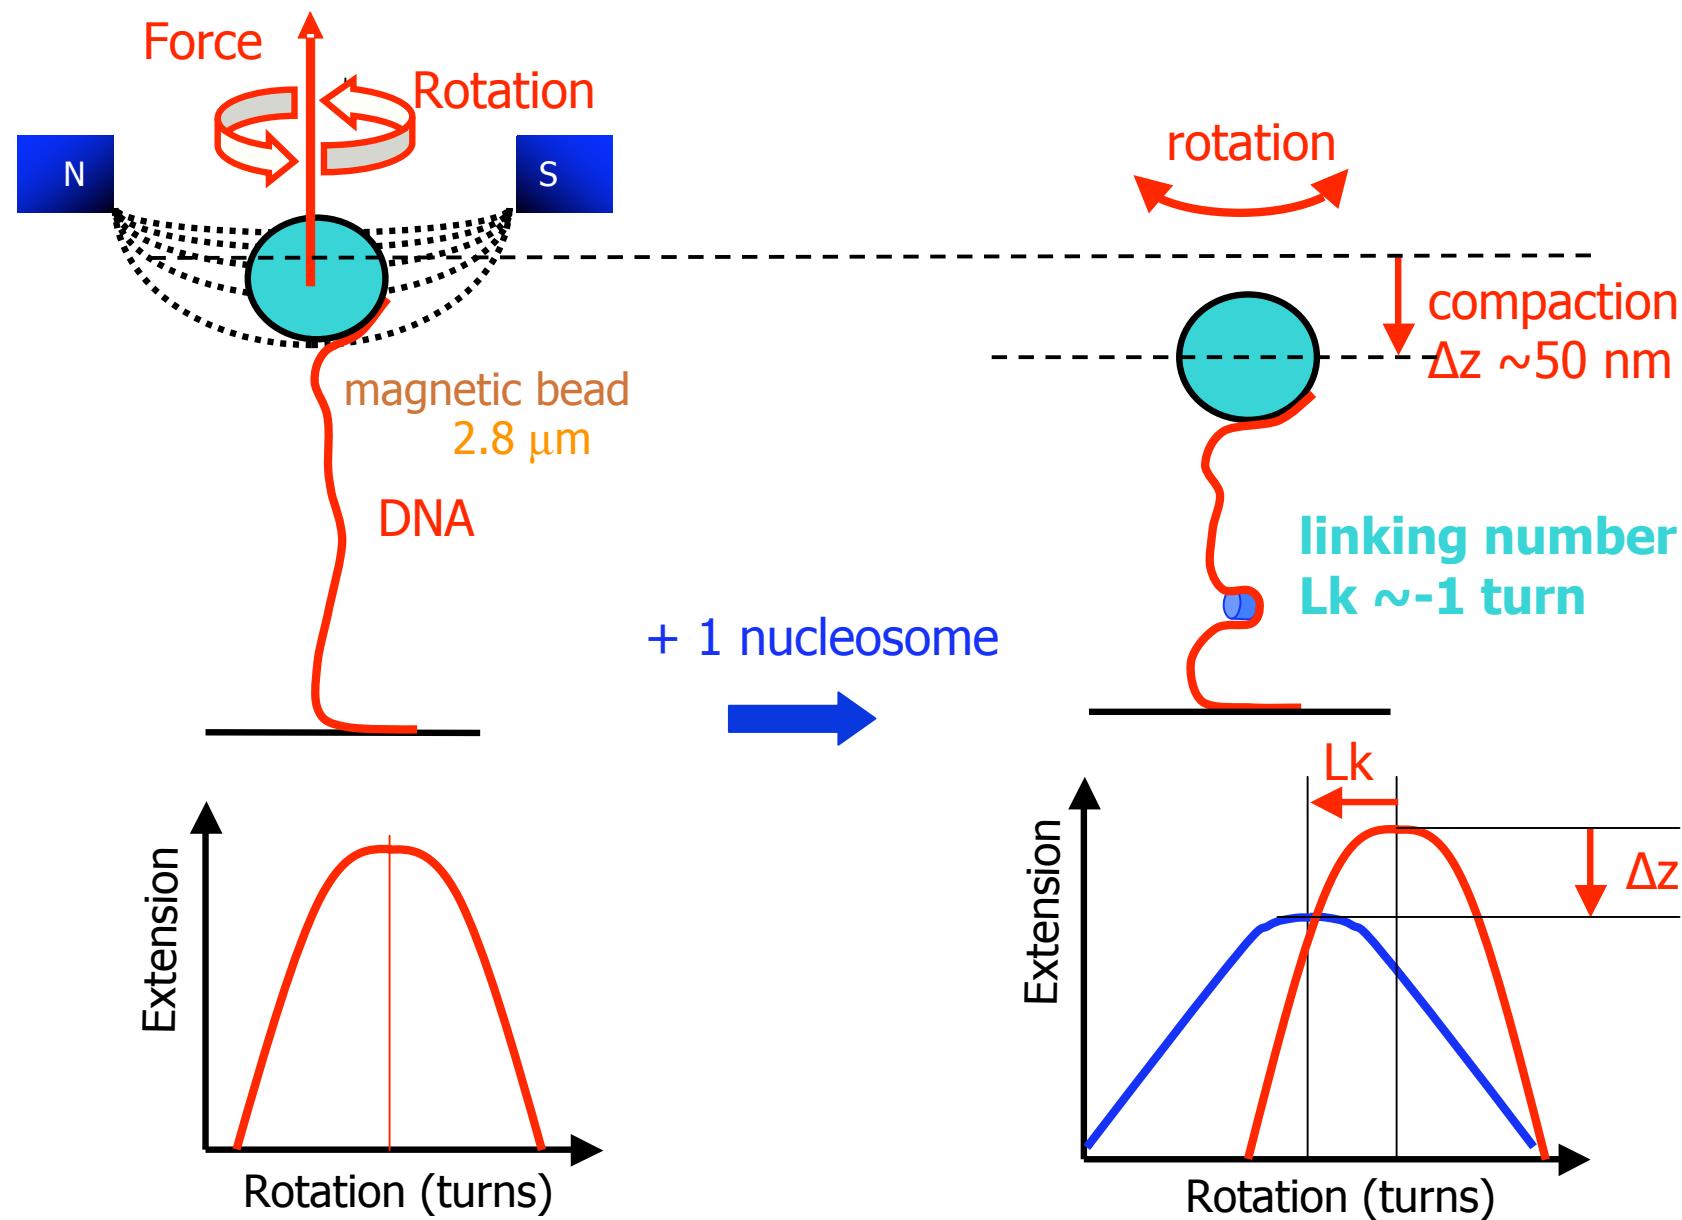

4. what about nucleosomes?

Animation by Hua Wong

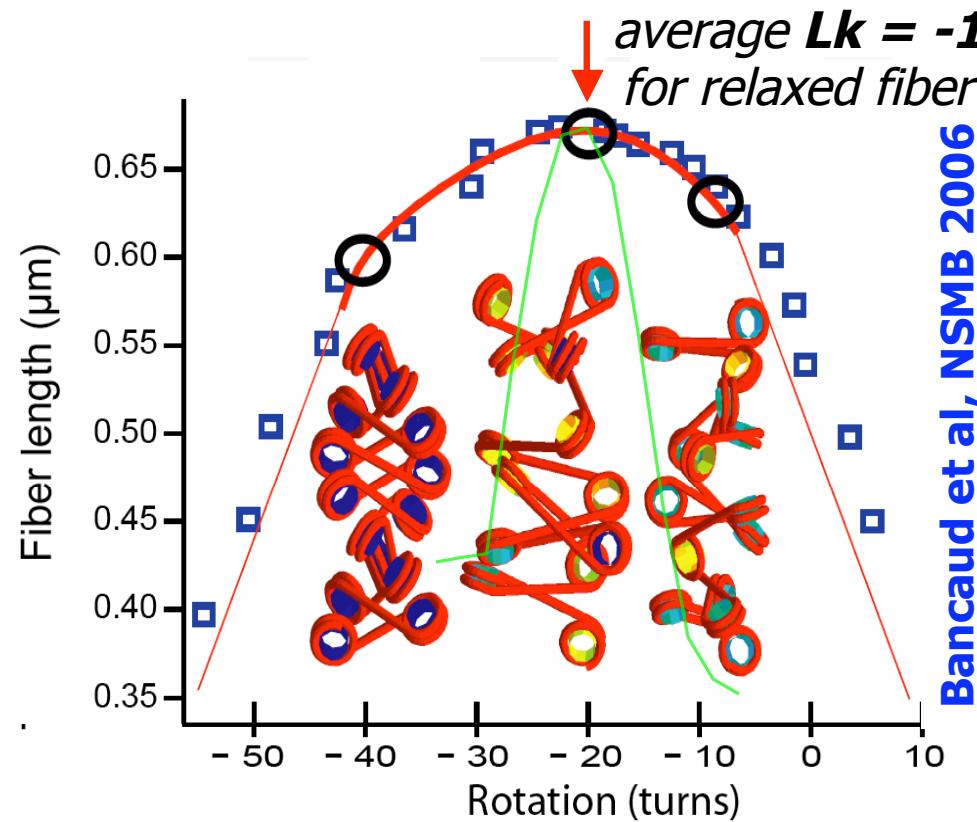

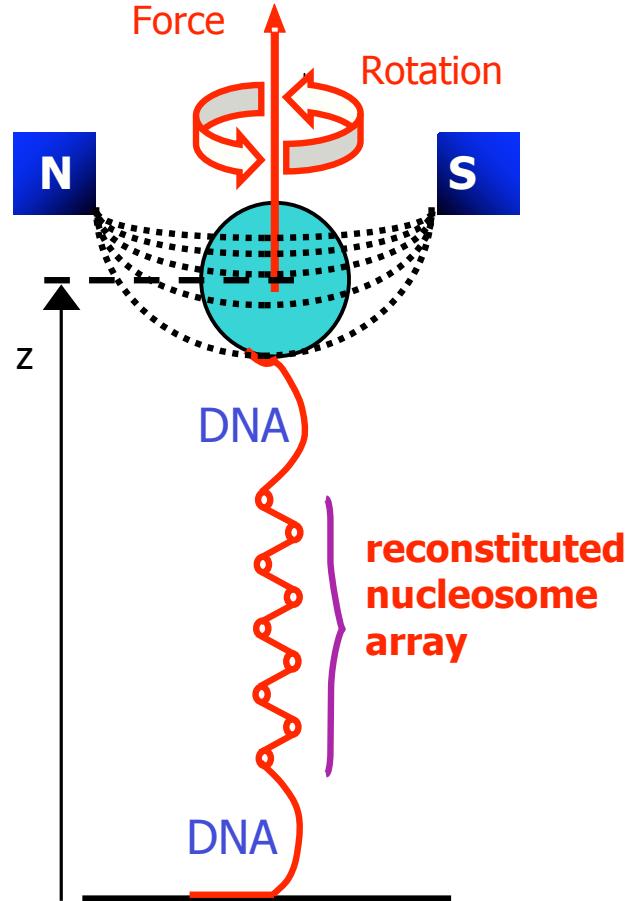

5. probing nucleosomes under torsion

by magnetic tweezers

5. probing nucleosomes under torsion

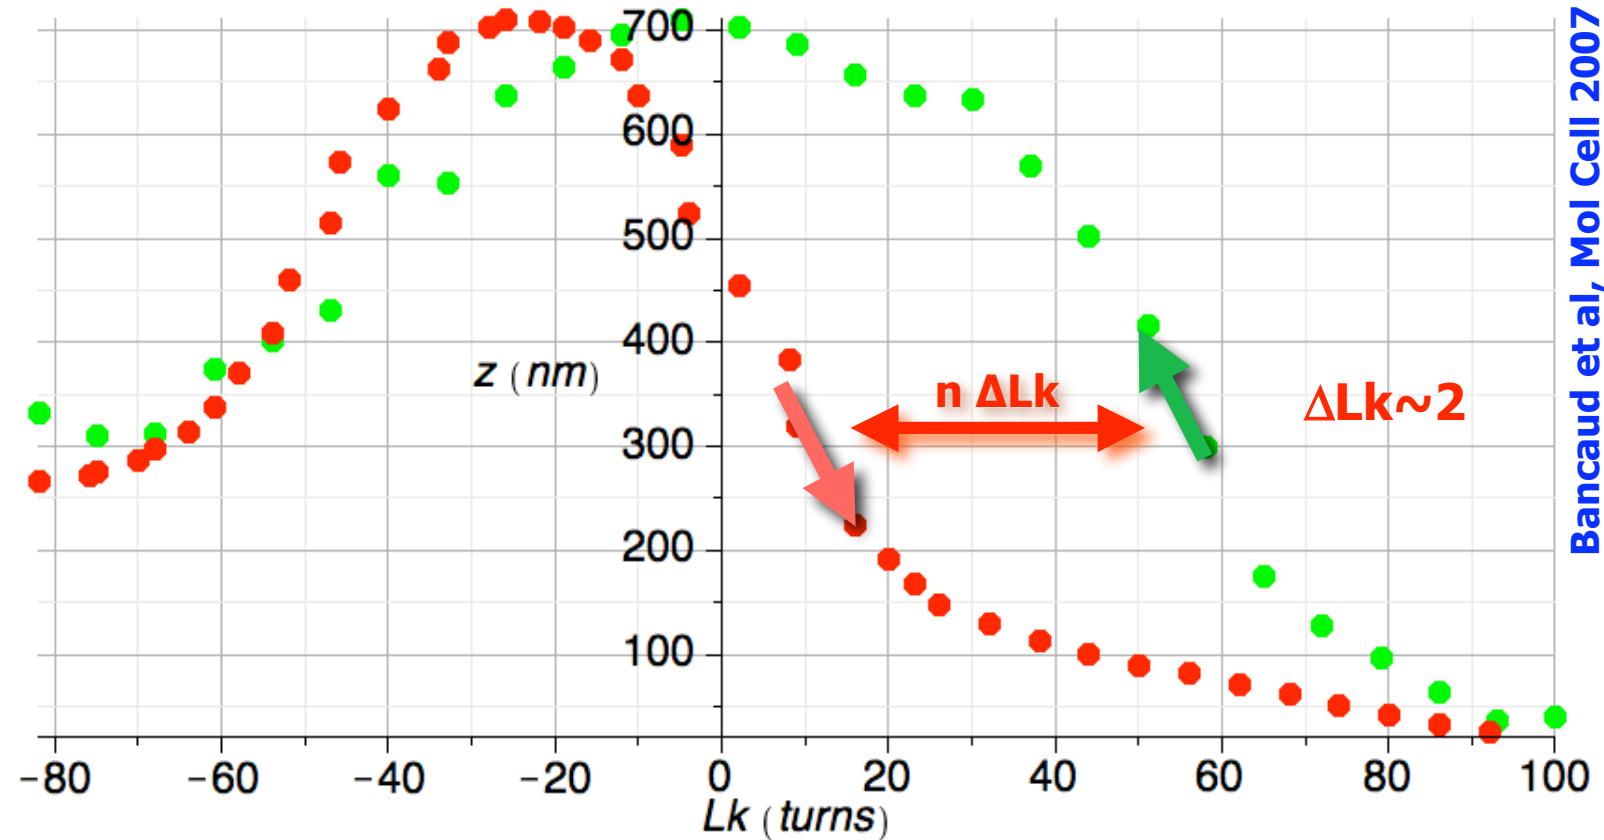

torque < 3 pN nm

fiber = topological buffer:
torque-dependent equilibrium between the 3 states of nucleosome

5. probing nucleosomes under torsion

RNA pol II torque > 5 pN nm: histeretic behavior

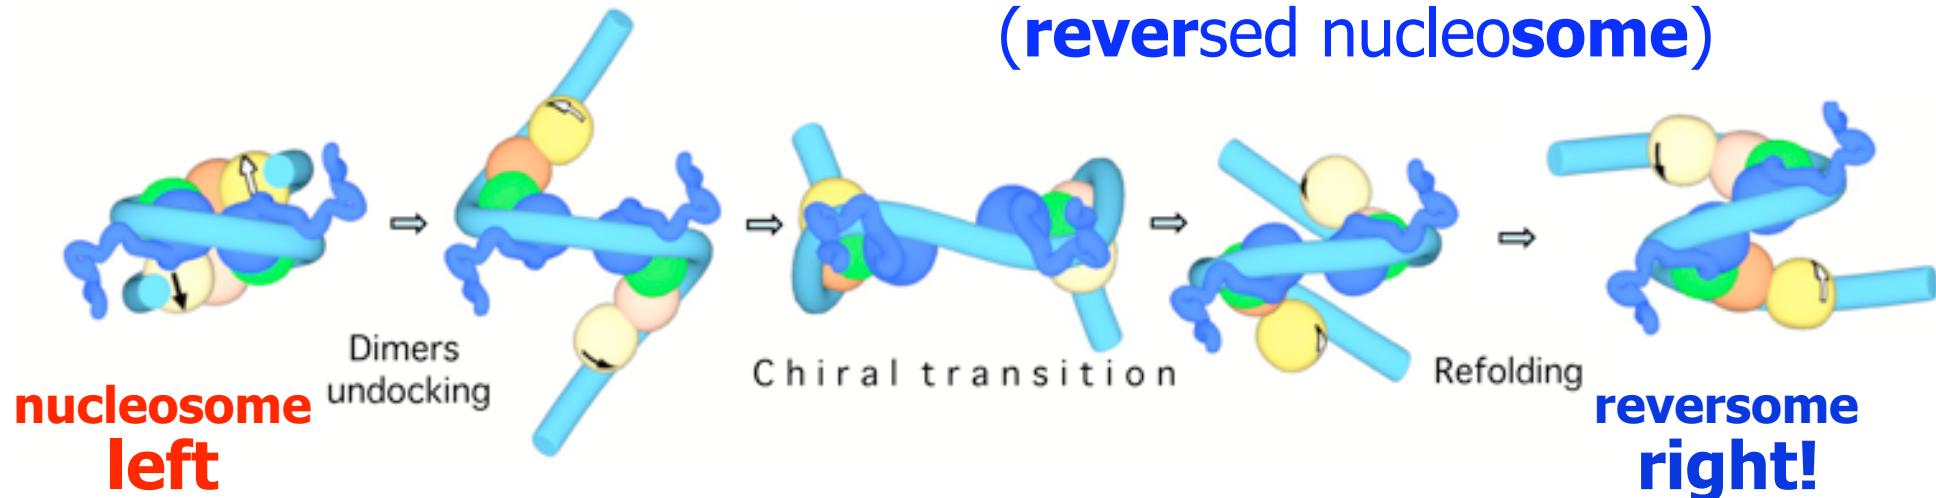

- not explained by nucleosome-nucleosome interactions
- compatible with a **nucleosome internal rearrangement: transition to a metastable altered state** with a larger (positive) ΔLk

5. probing nucleosomes under torsion

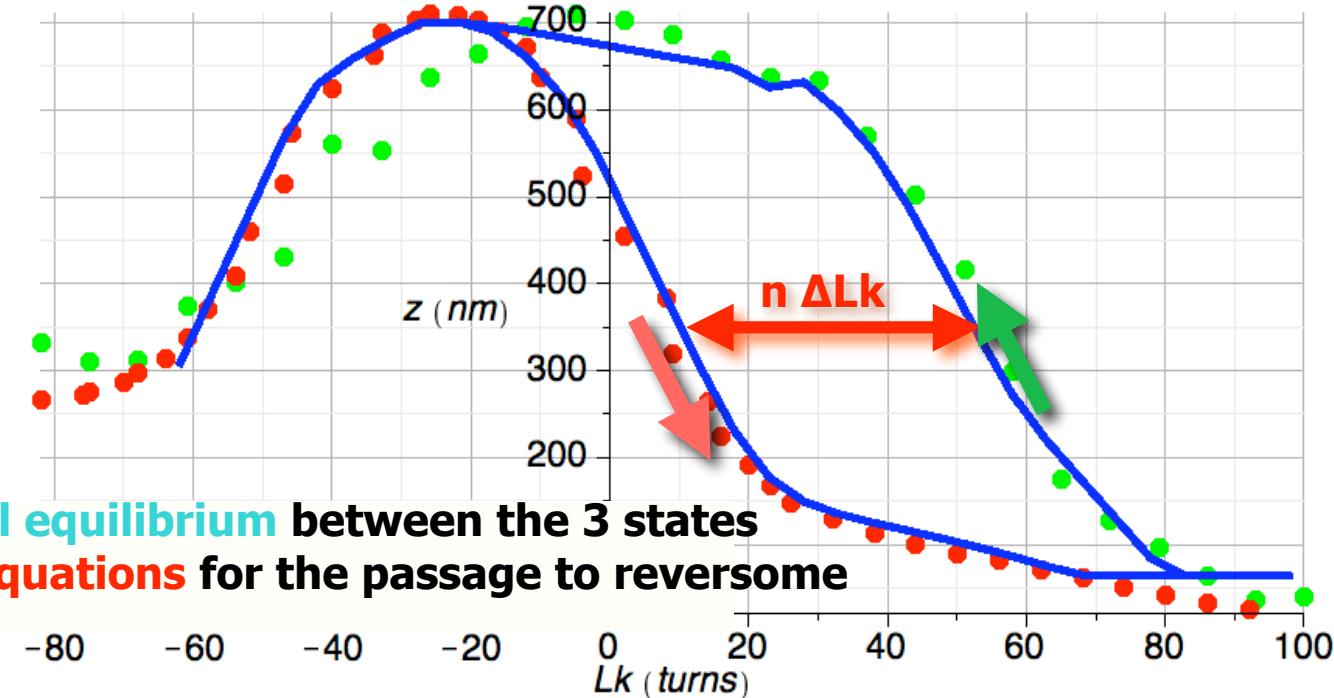

torque $> 5 \text{ pN nm}$:

transition to reversome
(reversed nucleosome)

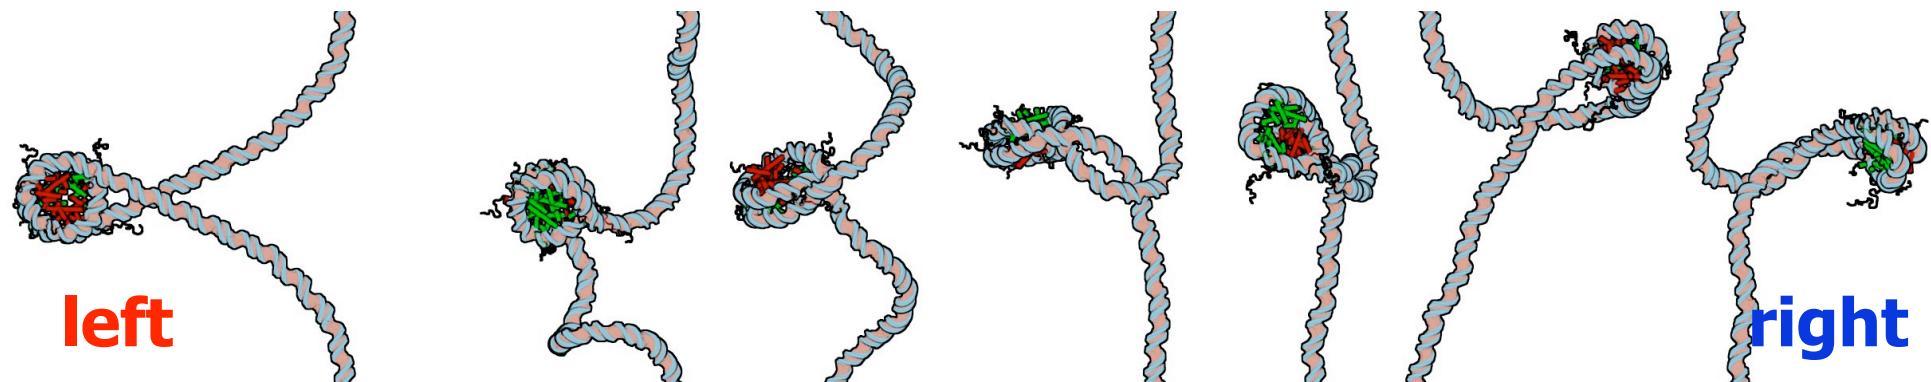

fit:

statistical equilibrium between the 3 states
+ kinetic equations for the passage to reversome

6. back to transcription

coarse grained (rigid body) numerical simulation

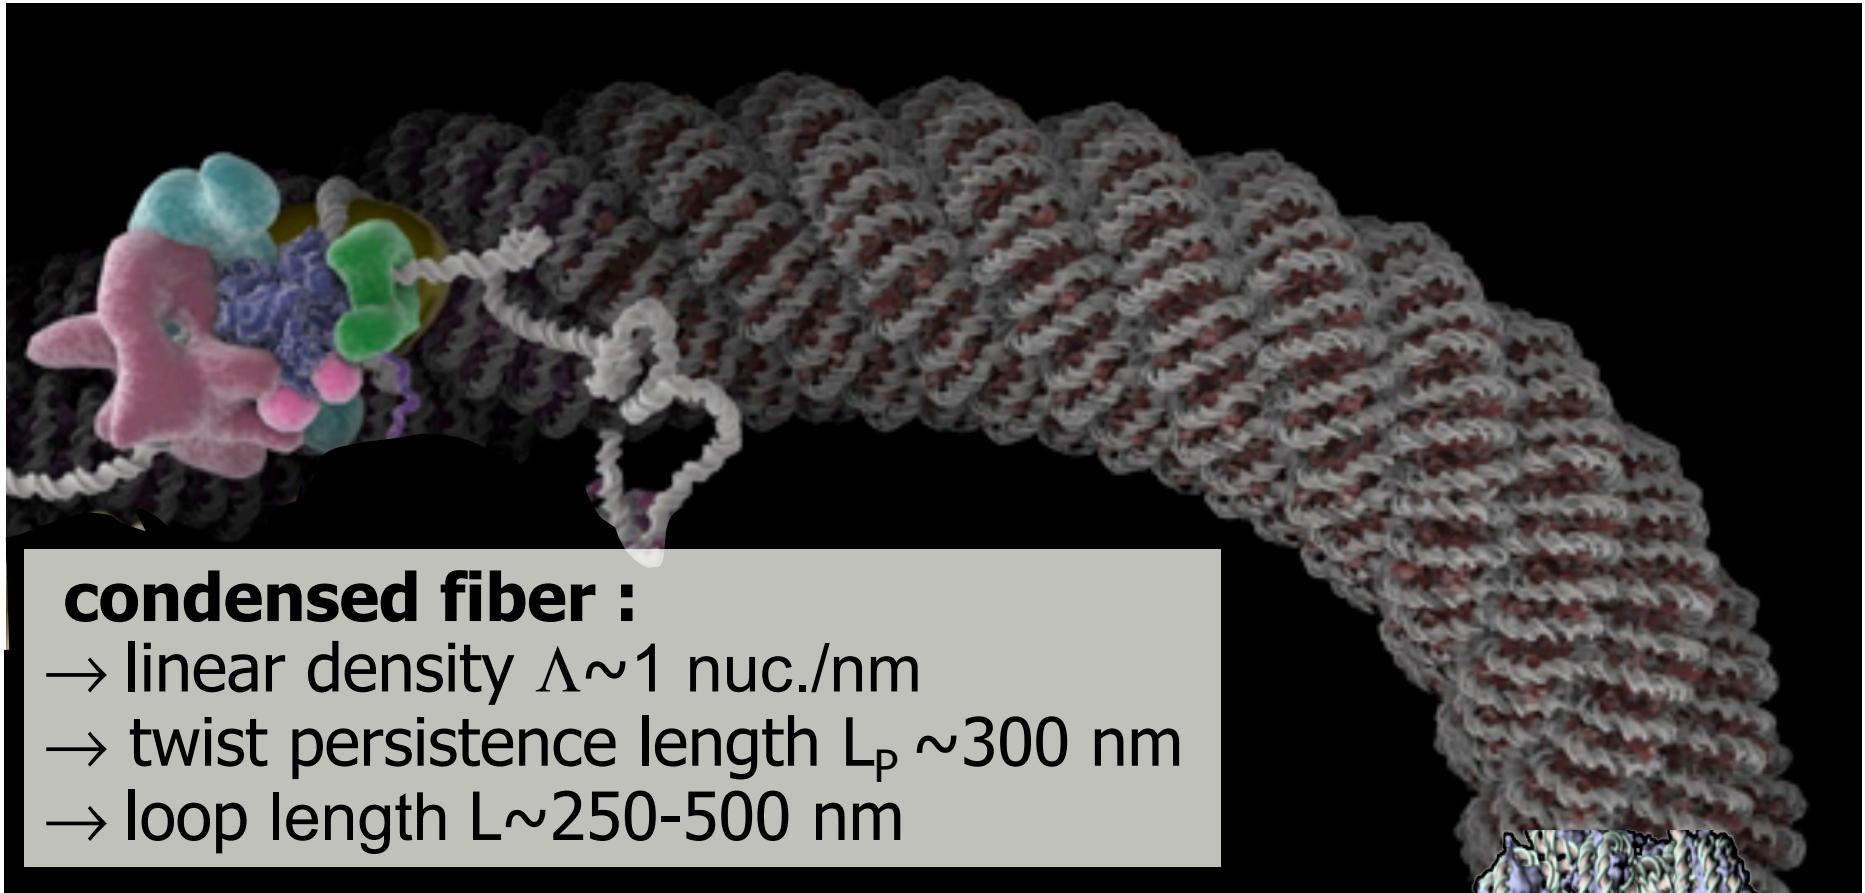

⇒ *need for the undocking of the H2A-H2B dimers*

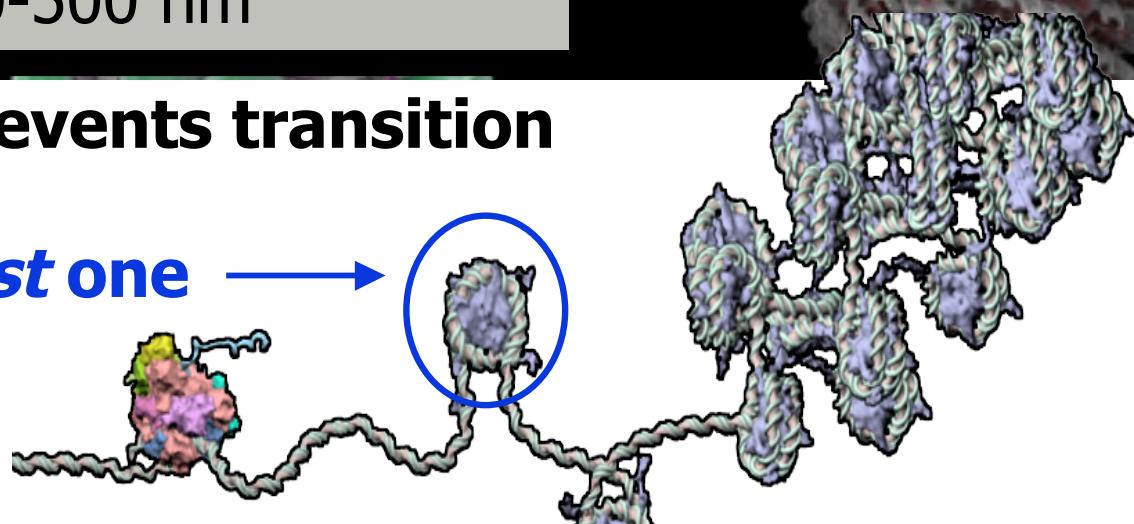

⇒ **reversome** as a “transparent” state of nucleosome?

6. back to transcription

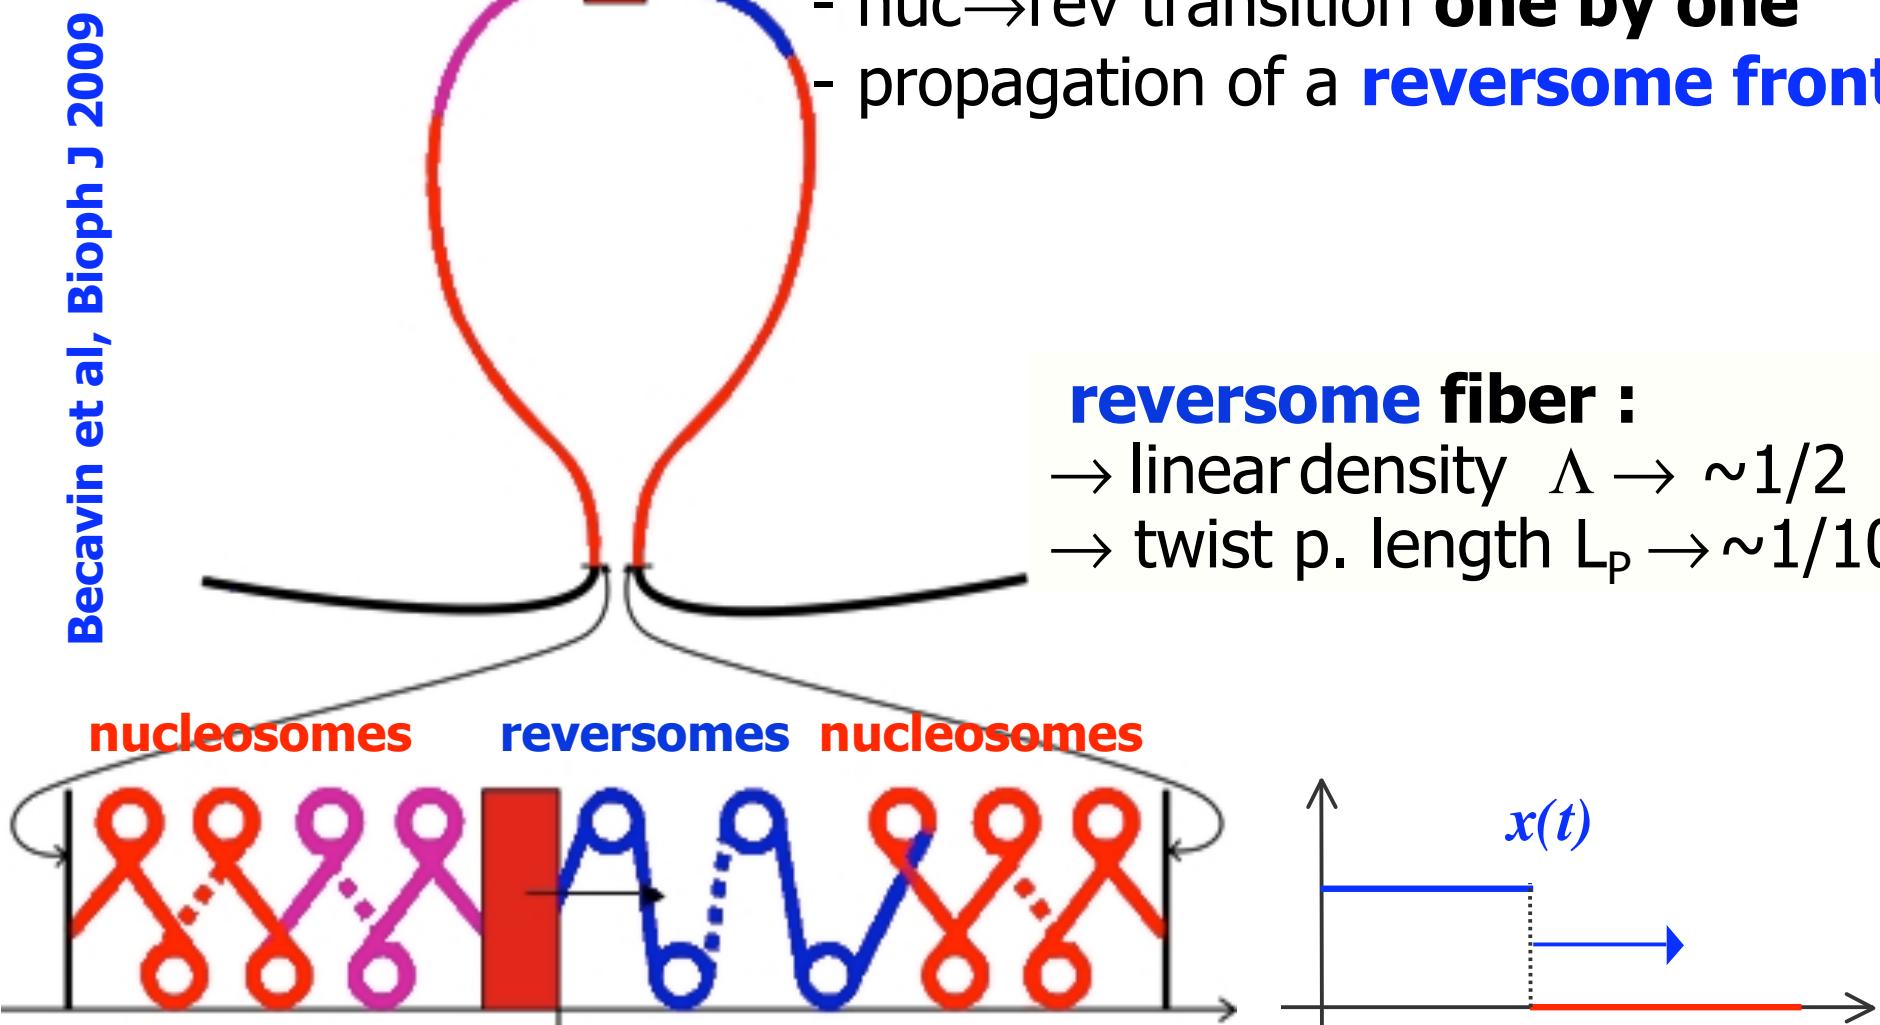

Steric hindrance prevents transition
to reversomes
...except for the **first one**

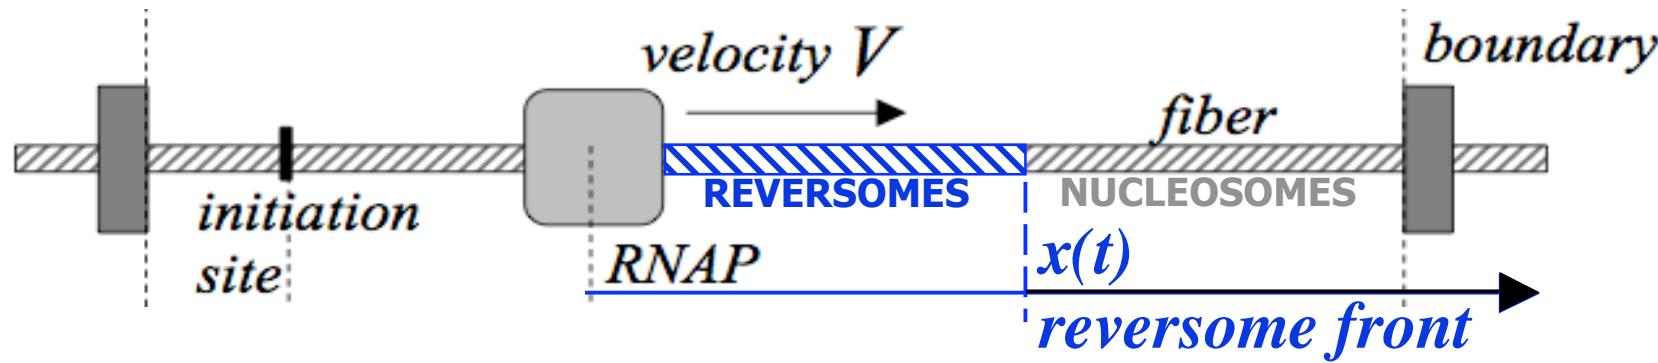

6. back to transcription

→ “domino effect”:

6. back to transcription

linking number conservation:

$$\frac{\omega_0 t}{2\pi} = \left[\Lambda \Delta L k + \frac{\tau}{2\pi} \right] \cdot x(t)$$

RNA pol rotation reversome fiber internal twist ($\Delta L k$ nucl \rightarrow rev)

Λ linear density

Γ applied torque

L_p twist pers. length

$$\tau = \frac{\Gamma}{L_p k_B T} \text{ fiber torsion}$$

τ_c critical torsion

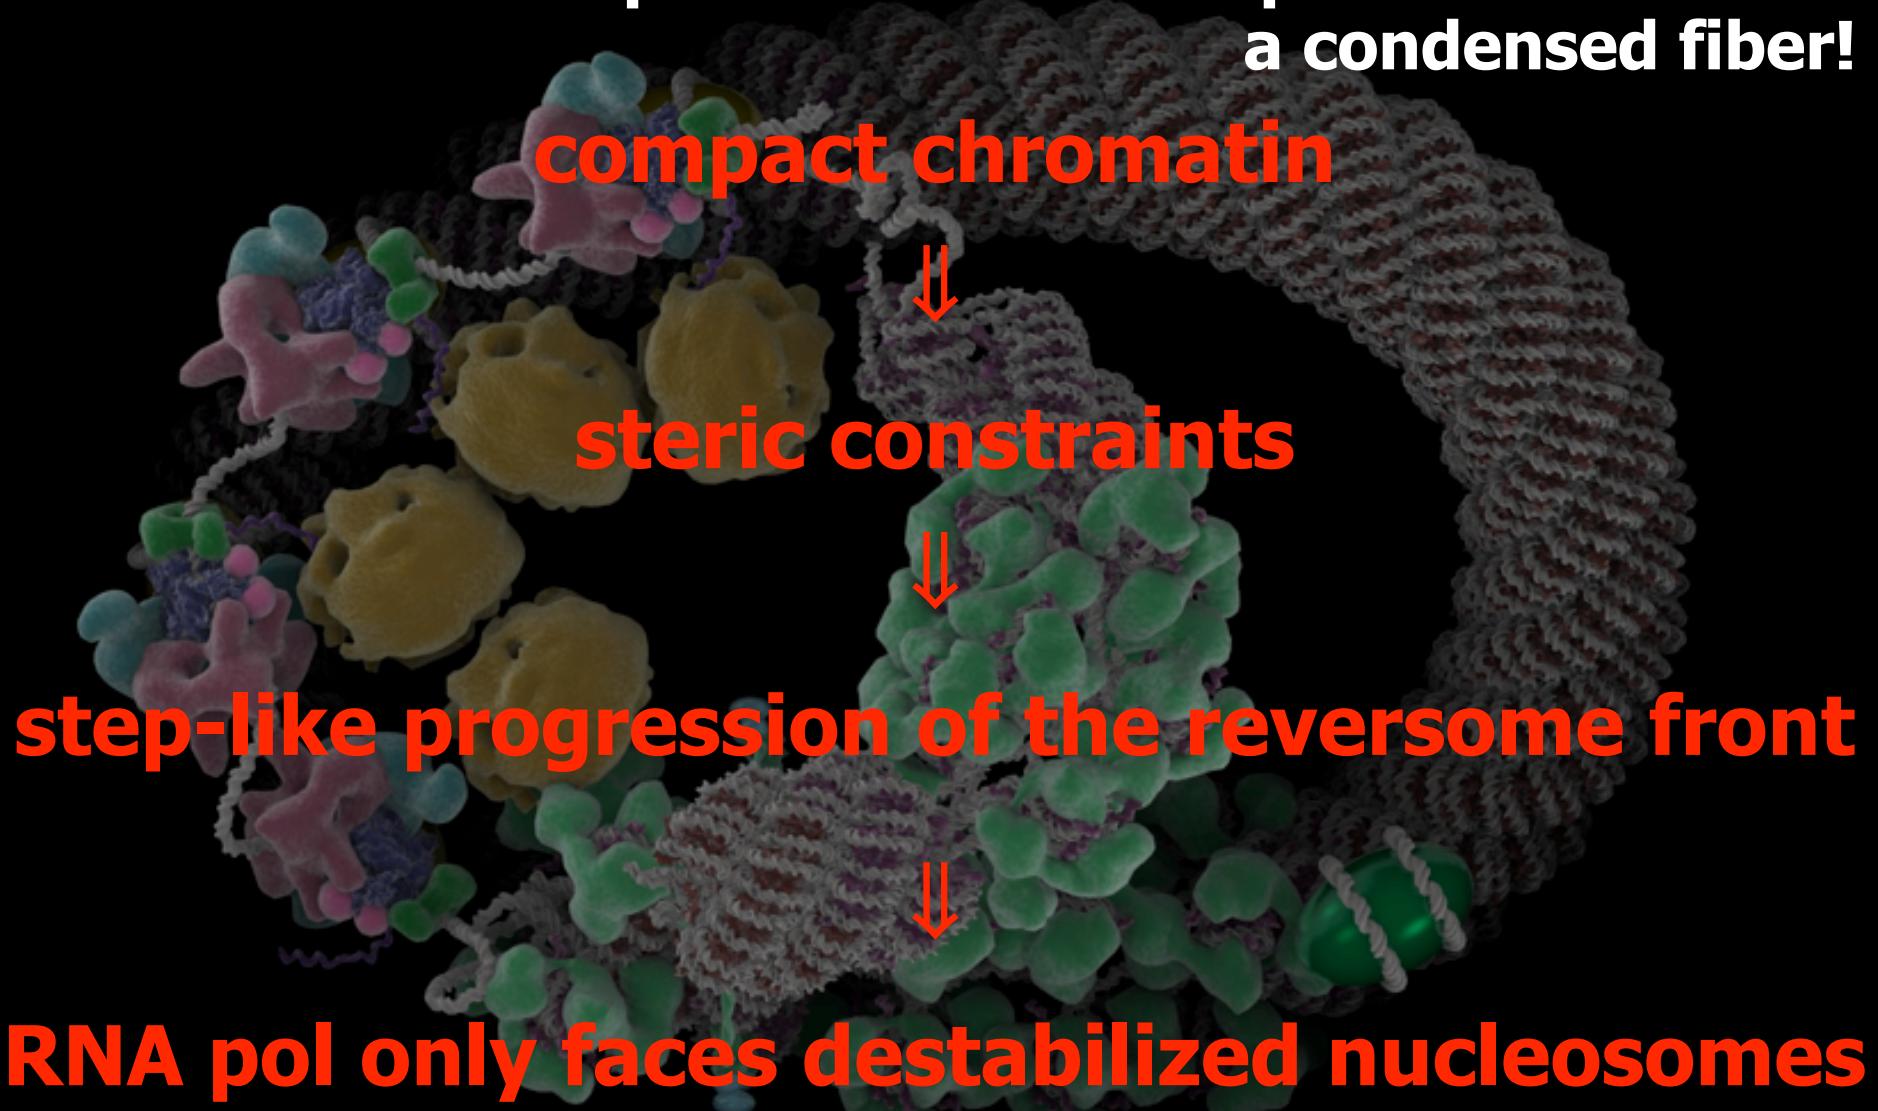

reversome front progression:

$$x(t) = v t + c, \quad v = \frac{\omega_0}{2\pi \Lambda \Delta L k + \tau_c} \approx \frac{\omega_0 / 2\pi}{\Lambda \Delta L k}$$

$$\rightarrow v = 1 \text{ nucl./s} \\ = 200 \text{ bps/s}$$

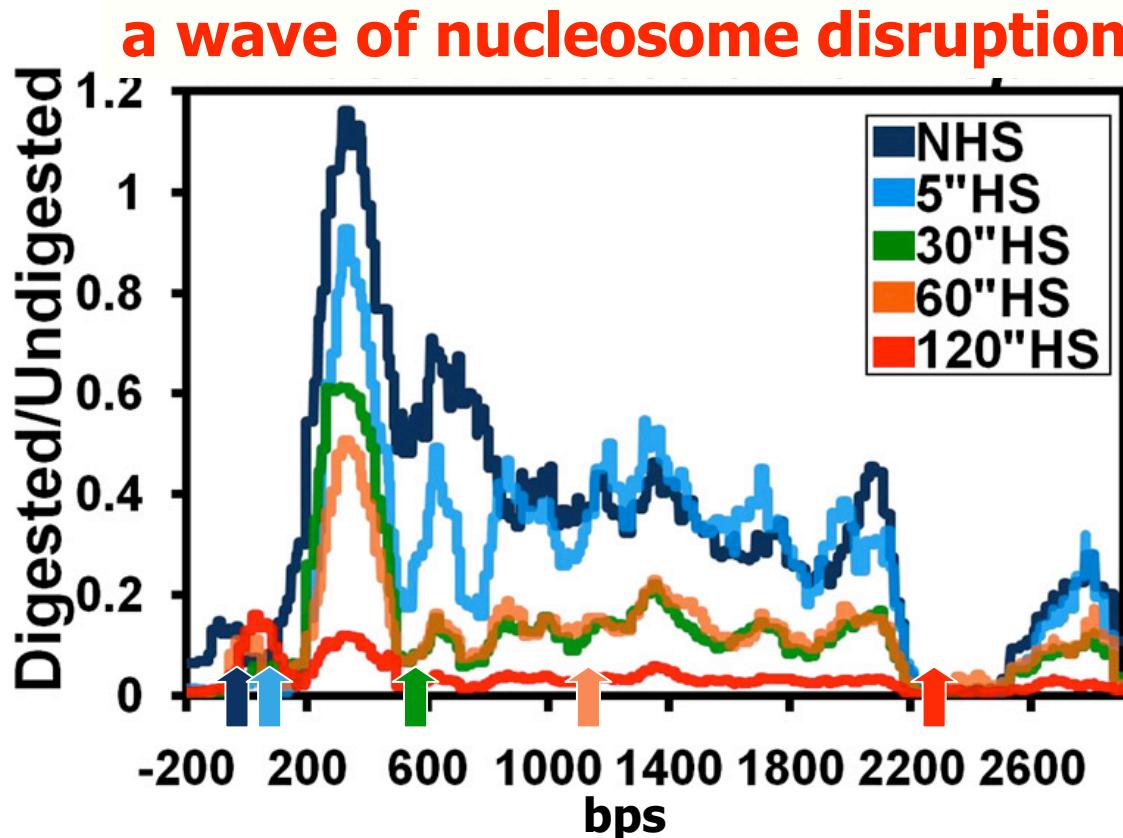

7. resulting scenario

a counter-intuitive prediction: transcription is easier in
a condensed fiber!

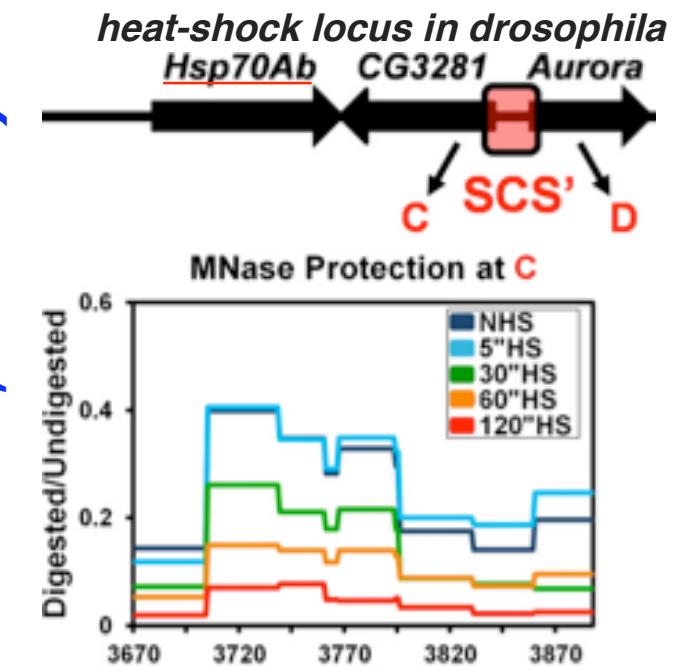

7. resulting scenario

first comparison with experiments !

(Petesh and Lis, Cell 2008)

**30'' : all the loop
and only the loop**

reversome-wave
interpretation:

- RNA pol at start
- 100 bps elongation → 10 turns, 5 rev., 1000 bps
- 600 bps elongation → 60 turns, 30 rev., 6000 bps
- 1200 bps elongation → 120 turns, 60 rev., 12000 bps
- ...
